

answered
t of
question

Differentiate business key and surrogate key using an example.

surrogate key can uniquely identify a row because it generate a unique key for each row, although a two rows get duplicate data it can be identified. But business key cannot do that always. Also the surrogate key can track the changes more efficiently than business key

eg: in type 2 of SCD, if customer changes its age, then a new record of customer will be inserted with the changed age, but other data in the row are same. In such cases business key can duplicate, but surrogate key creates a new unique key.

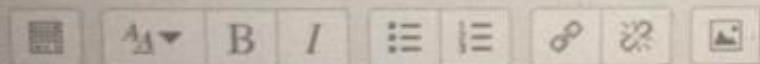

Surrogate key has no business meaning, business key has a meaning, because most of the time surrogate key is an auto-incremental integer

eg: surrogate key column: customerkey = 0

business key column: customerid = CUS202008

g question

What is a Data Mart and in what situation a business enterprise can have a data warehouse and a data mart?

Data mart

It is a subset of the data warehouse. Created specially for separate line of business (Marketing Department, Finance Department etc).

It can also work independently and also it can integrate data directly from sources.

A business enterprise can have a data warehouse when it needs a unified way of organizing and representing data. Helps for the decision support services to get decisions easily as it has a unified approach.

Data mart is used when the company wants separate independent subsets of data warehouses.

Question 19

Not yet answered

Marked out of 1.00

Flag question

Briefly state the purpose of Change Data Capture (CDC) with reference to initial and incremental data loading in Data Warehouse.

Initial Data loading is extracting completely from the source and in that instance, no need to keep a track of changes to the data source since last successful extraction.

Incremental is when only the changes are extracted and that is when CDC is important because even though in initial loading does not prioritize changes, incremental does. And CDC is important as it is the process of capturing changes made at the data source and applying them throughout the enterprise.
